Support Vector Machines Exercises

Simone Collier

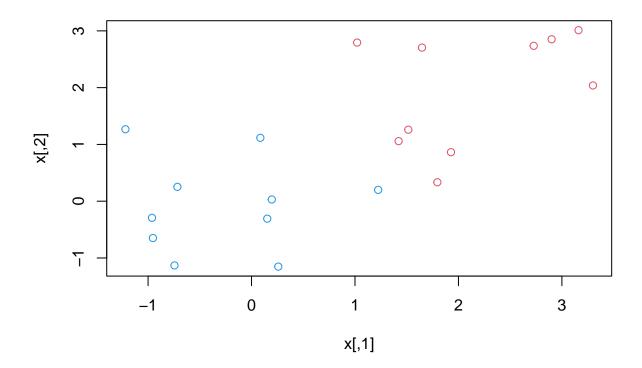

Maximal Margin Classifier

Start by loading the packages we need. If you need to install the packages first then run install.packages("PACKAGENAME") in your console before running the code chunk.

```
library(e1071)
library(ISLR2)
```

We want to generate a data set with two dimensional observations X. Each observation belongs to one of two classes $\{-1,1\}$.

```
set.seed(3)
# Create a matrix of 20 observations where each row is an observation.
x <- matrix(c(rnorm(20, mean = 0), rnorm(20, mean = 2)), ncol = 2, byrow = TRUE)
# Create a vector of the classes of the observations
y <- c(rep(-1, 10), rep(1, 10))
plot(x, col = (3 - y))</pre>
```

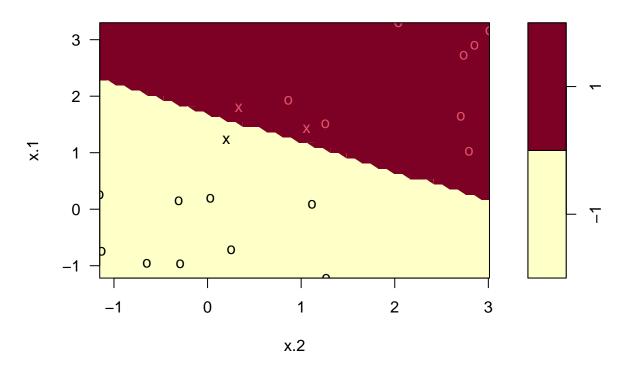

We can see that the observations from each class can be separated by a hyperplane so we can use the maximal margin classifier. To start let's put our observations in a data frame with the response coded as a factor.

```
data \leftarrow data.frame(x = x, y = as.factor(y))
```

Now we can use the svm() function from the e1071 library to fit our classifier. We choose kernal = "linear" set cost as a very large number (these parameters will be explained more later. We specify scale = FALSE so the function does not scale each feature to have mean zero and standard deviation one.

```
mmcfit <- svm(y ~ ., data = data, kernel = "linear", cost = 1e10, scale = FALSE)
plot(mmcfit, data)</pre>
```

SVM classification plot

The plot makes the decision boundary look jagged but it is indeed linear. Note that x[, 1] and x[, 2] have switched axes compare to our last plot. The support vector are plotted as crosses and the remaining observations are circles.

summary(mmcfit)

```
##
## Call:
## svm(formula = y ~ ., data = data, kernel = "linear", cost = 1e+10,
##
       scale = FALSE)
##
##
## Parameters:
##
      SVM-Type:
                 C-classification
##
    SVM-Kernel:
                 linear
##
                1e+10
          cost:
##
  Number of Support Vectors: 3
##
##
##
    (12)
##
##
## Number of Classes: 2
##
## Levels:
   -1 1
##
```

This tells us that there are 3 support vectors with (1 2) indicating there are 1 from the first class and 2 from the second.

We can create a set of test observations using the same criteria as our training set.

```
set.seed(2)
xtest <- matrix(c(rnorm(20, mean = 0), rnorm(20, mean = 2)), ncol = 2, byrow = TRUE)
ytest <- c(rep(-1, 10), rep(1, 10))
testdata <- data.frame(x = xtest, y = as.factor(ytest))</pre>
```

Now we can try predicting the class labels of our test observations using our best model.

```
ypred <- predict(mmcfit, testdata)
table(predict = ypred, truth = testdata$y)

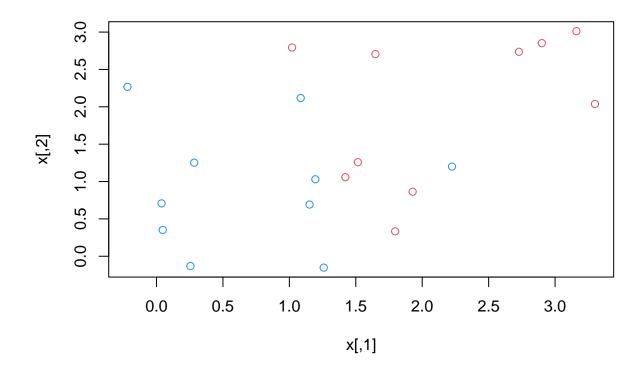

## truth
## predict -1 1
## -1 9 1
## 1 1 9</pre>
```

So all but 2 of the test observations are classified correctly.

Support Vector Classifier

We will generate a data set with two dimensional observations X. Each observation belongs to one of two classes $\{-1,1\}$. This time we want a data set that is not separable by a hyperplane.

```
set.seed(3)
# Create a matrix of 20 observations where each row is an observation.
x <- matrix(c(rnorm(20, mean = 1), rnorm(20, mean = 2)), ncol = 2, byrow = TRUE)
# Create a vector of the classes of the observations
y <- c(rep(-1, 10), rep(1, 10))
plot(x, col = (3 - y))</pre>
```

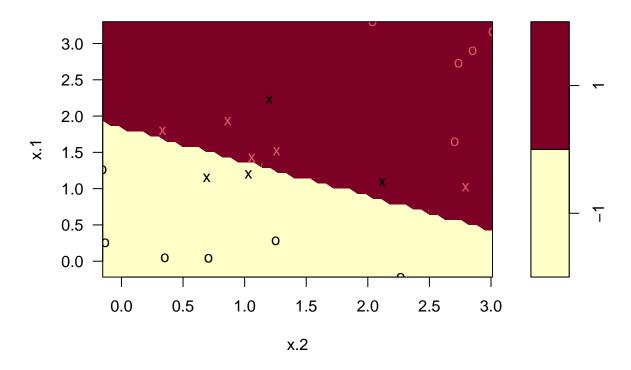

We can see that the observations from each class cannot be separated by a hyperplane so we can't use the maximal margin classifier. We will fit a support vector classifier instead. To start let's put our observations in a data frame with the response coded as a factor.

```
data <- data.frame(x = x, y = as.factor(y))</pre>
```

Now we can use the svm() function to fit our classifier. We choose kernal = "linear" to specify we want to fit a support vector classifier and set cost = 8.

```
svcfit <- svm(y ~ ., data = data, kernel = "linear", cost = 8, scale = FALSE)
plot(svcfit, data)</pre>
```

SVM classification plot

summary(svcfit)

```
##
## Call:
## svm(formula = y ~ ., data = data, kernel = "linear", cost = 8, scale = FALSE)
##
##
##
  Parameters:
##
      SVM-Type: C-classification
##
    SVM-Kernel:
                 linear
##
          cost:
##
##
  Number of Support Vectors: 9
##
    (45)
##
##
##
## Number of Classes: 2
##
## Levels:
   -1 1
```

There are 9 support vectors with 4 from the first class and 5 from the second.

Try fitting a support vector classifier with a smaller value for cost. Compare the results including the number of support vectors to the above two classifiers. From this information

explain the relationship between the cost parameter and C as we have described in the slides.

We will use the tune() function from the e1071 library to perform cross-validation to choose the best value for cost.

```
set.seed(1)
tune.out <- tune(svm, y ~ ., data = data, kernel = "linear", ranges = list(cost = c(0.001, 0.01, 0.1, 1
summary(tune.out)
##
## Parameter tuning of 'svm':
## - sampling method: 10-fold cross validation
##
## - best parameters:
##
   cost
##
      10
##
## - best performance: 0.15
## - Detailed performance results:
##
      cost error dispersion
## 1 1e-03 0.55 0.4972145
## 2 1e-02 0.55 0.4972145
           0.35 0.3374743
## 3 1e-01
## 4 1e+00 0.20 0.2581989
## 5 5e+00 0.20 0.2581989
## 6 1e+01 0.15 0.2415229
## 7 1e+02 0.15 0.2415229
```

This tells us that cost = 10 results in the lowest cross-validation error rate. The best model found by tune() can be accessed using:

```
bestsvc <- tune.out$best.model
summary(bestsvc)</pre>
```

```
##
## Call:
## best.tune(METHOD = svm, train.x = y \sim ., data = data, ranges = list(cost = c(0.001,
       0.01, 0.1, 1, 5, 10, 100)), kernel = "linear")
##
##
##
## Parameters:
##
      SVM-Type:
                 C-classification
##
   SVM-Kernel:
                 linear
##
          cost:
##
## Number of Support Vectors: 9
##
##
   (45)
##
##
## Number of Classes: 2
```

```
##
## Levels:
## -1 1
```

We can create a set of test observations using the same criteria as our training set.

```
set.seed(1)
xtest <- matrix(c(rnorm(20, mean = 1), rnorm(20, mean = 2)), ncol = 2, byrow = TRUE)
ytest <- c(rep(-1, 10), rep(1, 10))
testdata <- data.frame(x = xtest, y = as.factor(ytest))</pre>
```

Now we can try predicting the class labels of our test observations using our best model.

```
ypred <- predict(bestsvc, testdata)
table(predict = ypred, truth = testdata$y)

## truth
## predict -1 1
## -1 4 1
## 1 6 9</pre>
```

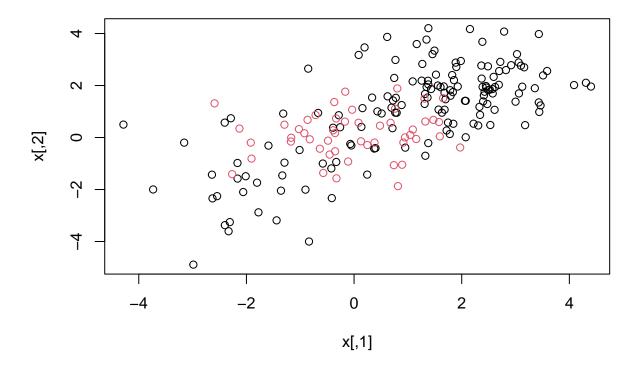

So 13 out of 20 observations are correctly classified.

Support Vector Machine

We will use the svm() function to fit an SVM with a non-linear kernel. We first generate some data with a non-linear class boundary.

```
set.seed(1)
x <- matrix(c(rnorm(200, mean = 2), rnorm(50, mean = -2), rnorm(150)), ncol = 2, byrow = TRUE)
y <- c(rep(1, 150), rep(2, 50))

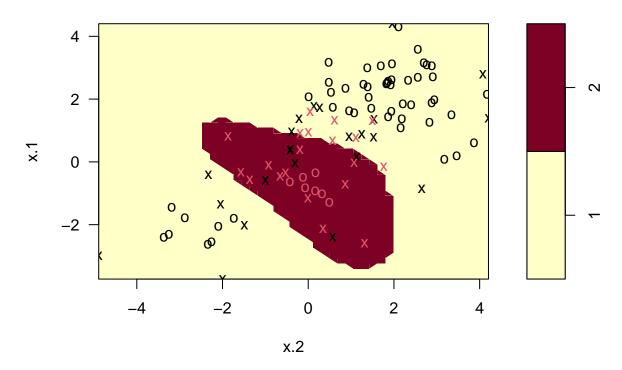

data <- data.frame(x = x, y = as.factor(y))
plot(x, col = y)</pre>
```

We randomly split our data set into training and test sets. Then we fit the training data with a radial kernel. The argument gamma controls how non-linear the fit with the radial kernel can be.

```
train <- sample(200, 100)
svmfit <- svm(y ~ ., data = data[train, ], kernal = "radial", cost = 1, gamma = 1)
plot(svmfit, data[train, ])</pre>
```

SVM classification plot

summary(svmfit)

```
##
## Call:
## svm(formula = y ~ ., data = data[train, ], kernal = "radial", cost = 1,
       gamma = 1)
##
##
##
##
   Parameters:
##
      SVM-Type: C-classification
##
    SVM-Kernel:
                radial
##
          cost:
##
  Number of Support Vectors: 43
##
##
    (23 20)
##
##
## Number of Classes: 2
##
## Levels:
## 1 2
```

Perform cross-validation using tune() to select the best choice of gamma and cost. Try the ranges cost = c(0.1, 1, 10, 100, 1000) and gamma = c(0.5, 1, 2, 3, 4). Output the best model.

Using the best model, predict the responses for the test set. What percent of observations were misclassified by this SVM?

The svm() function has the capability to perform classification when there are more than two response classes. In this case the svm() will use the one-versus-one approach.

Support vector regression is also possible with the svm() function when the response is quantitative!

These exercises were adapted from : James, Gareth, et al. An Introduction to Statistical Learning: with Applications in R, 2nd ed., Springer, 2021.
